

## **ABSTRACT**

Described is a method for adapting an application sharing system for a network of computers according to user specific requirements. The method includes dynamically configuring system components and manually implementing user specific preferences to achieve a better user experience than is possible in typical application sharing systems. Users can

5 configure the application sharing system based on their individual needs, and may need to modify their settings based on changing operating environments or usage patterns. The application sharing system can be dynamically configured based on content, current tasks, and changes in network conditions. System administrators can configure the application sharing system according to their general needs without preempting the needs of an individual user.
